Manuscript: Disclosed Intelligence: A Large-Sample Measurement of AI Disclosure in U.S. Investment Adviser Fiduciary Filings **Target:** Frontiers in Artificial Intelligence (Original Research)

This manuscript fits Frontiers in Artificial Intelligence because it advances the empirical measurement of how artificial intelligence is described and disclosed in high-stakes regulatory text, and it validates large language models as a scientific measurement instrument. Using SEC Form ADV Part 2A brochures for a stratified random sample of 400 U.S. investment advisers, we build a preregistered five-label typology and apply it with a large language model, then establish reliability through same-family reproducibility and an independent, blinded cross-family re-coding (any-use Cohen's kappa 0.65). The study contributes a reproducible AI-classification instrument, the first large-sample estimate of disclosed AI use and its size and adviser-type gradient with design-based inference and survey weighting, an enforcement-anchored AI-washing exposure screen, and a brochure-versus-marketing venue comparison. It speaks directly to the journal's interest in trustworthy, auditable applications of AI to text at scale, in the reliability of LLM annotation against independent references, and in AI governance and disclosure. All data, code, prompts, and coding sheets are released as a public reproducibility artifact so the measurement can be independently audited and extended.
